Solid-state memory capable of nonvolatile storage of charge, particularly in the form of EEPROM and flash EEPROM packaged as a small form factor card, has become the storage of choice in a variety of mobile and handheld devices, notably information appliances and consumer electronics products. Unlike RAM (random access memory) that is also solid-state memory, flash memory is non-volatile, and retains its stored data even after power is turned off. Also, unlike ROM (read only memory), flash memory is rewritable similar to a disk storage device. Flash memory typically utilizes one of two basic architectures known as NOR flash and NAND. The designation is derived from the logic used to read the devices. In NOR flash architecture, a logical column of memory cells is connected in parallel with each memory cell connected to a bit line. In NAND flash architecture, a column of memory cells is connected in series with each memory cell connected to a bit line. Flash memory devices are usually treated as SCSI devices by host computer systems. Although the access time of flash memory is typically slower than RAM, flash memory accesses can proceed at any time without latency, unlike battery-powered microcontrollers that are constrained to operate only during certain times of a limited power supply. Flash memory devices, or at least their data-storage elements, need to be replaced when the media/storage is damaged, as a necessary part of flash memory media, such as a storing medium, has limited life span. Therefore, users have been attempting to reduce the incidence of failure of a memory medium, as well as the incidence of failures of the memory devices themselves. One approach has been to check the storage medium for defects in a
