Target size and target processing sequence determine functional asymmetries of visually guided saccades. Asymmetries in the left and right hemispheres can be revealed during visually guided movements, such as saccades. Whereas the neurocognitive mechanisms of saccades that switch between hemispheres are well understood, little is known about the cognitive mechanisms that are responsible for the asymmetries that develop during or after saccades. In the present study, we examined these mechanisms by comparing the saccadic targeting of peripheral cues that are processed in the ipsilateral and contralateral hemispheres. When first-order saccadic selection could not be avoided, the target was found on the contralateral side, which indicates that, even without immediate visual feedback, information from the contralateral side was used for saccadic selection. A second experiment with partially visible peripheral targets demonstrated that target properties determined which hemisphere was used for targeting and that when the target was small, saccades were often asymmetrical. Target properties that produced successful saccades were identical, except for the sequence in which targets were presented. When targets were presented in the order L-T-R (gray-white-gray), in which the L target preceded the T target, successful saccades were predominantly made to the L target; when targets were presented in the reversed order (
